

NAME

ddb - configure DDB kernel debugger properties

SYNOPSIS

ddb capture [-M *-core*] [-N *-system*] **print**

ddb capture [-M *-core*] [-N *-system*] **status**

ddb script *scriptname*

ddb script *scriptname=script*

ddb scripts

ddb unscript *scriptname*

ddb *pathname*

DESCRIPTION

The **ddb** utility configures certain aspects of the ddb(4) kernel debugger from user space that are not configured at compile-time or easily via sysctl(8) MIB entries.

To ease configuration, commands can be put in a file which is processed using **ddb** as shown in the last synopsis line. An absolute *pathname* must be used. The file will be read line by line and applied as arguments to the **ddb** utility. Whitespace at the beginning of lines will be ignored as will lines where the first non-whitespace character is '#'.

OUTPUT CAPTURE

The **ddb** utility can be used to extract the contents of the ddb(4) output capture buffer of the current live kernel, or from the crash dump of a kernel on disk. The following debugger commands are available from the command line:

capture [-M *core*] [-N *system*] **print**

Print the current contents of the ddb(4) output capture buffer.

capture [-M *core*] [-N *system*] **status**

Print the current status of the ddb(4) output capture buffer.

SCRIPTING

The **ddb** utility can be used to configure aspects of ddb(4) scripting from user space; scripting support is described in more detail in ddb(4). Each of the debugger commands is available from the command line:

script *scriptname*

Print the script named *scriptname*.

script *scriptname=script*

Define a script named *scriptname*. As many scripts contain characters interpreted in special ways by the shell, it is advisable to enclose *script* in quotes.

scripts

List currently defined scripts.

unscript *scriptname*

Delete the script named *scriptname*.

EXIT STATUS

The **ddb** utility exits 0 on success, and >0 if an error occurs.

EXAMPLES

The following example defines a script that will execute when the kernel debugger is entered as a result of a break signal:

```
ddb script kdb.enter.break="show pcpu; bt"
```

The following example will delete the script:

```
ddb unscript kdb.enter.break
```

For further examples, see the `ddb(4)` and `textdump(4)` manual pages.

SEE ALSO

`ddb(4)`, `mac_ddb(4)`, `textdump(4)`, `sysctl(8)`

HISTORY

The **ddb** utility first appeared in FreeBSD 7.1.

AUTHORS

Robert N M Watson

BUGS

Ideally, **ddb** would not exist, as all pertinent aspects of `ddb(4)` could be configured directly via `sysctl(8)`.
