NAME

devctl_process_running - Returns true when devctl has a consumer process running

SYNOPSIS

#include <sys/devctl.h>

bool
devctl_process_running(*void*);

DESCRIPTION

The **devctl_process_running** call returns *true* when a process has the devctl device open for reading, and *false* otherwise. One can assume from this that the default devd(8) or similar is running when *true* is returned. Some subsystems will send a message and allow userland to do something before proceeding with a default action if there's a timeout. This call allows those subsystems to do the default action right away when no process is running.

SEE ALSO

devd(8)
