

**NAME**

**getaddrinfo**, **freeaddrinfo** - socket address structure to host and service name

**SYNOPSIS**

```
#include <sys/types.h>
#include <sys/socket.h>
#include <netdb.h>
```

*int*

```
getaddrinfo(const char *hostname, const char *servname, const struct addrinfo *hints,
             struct addrinfo **res);
```

*void*

```
freeaddrinfo(struct addrinfo *ai);
```

**DESCRIPTION**

The **getaddrinfo**() function is used to get a list of addresses and port numbers for host *hostname* and service *servname*. It is a replacement for and provides more flexibility than the `gethostbyname(3)` and `getservbyname(3)` functions.

The *hostname* and *servname* arguments are either pointers to NUL-terminated strings or the null pointer. An acceptable value for *hostname* is either a valid host name or a numeric host address string consisting of a dotted decimal IPv4 address, an IPv6 address, or a UNIX-domain address. The *servname* is either a decimal port number or a service name listed in `services(5)`. At least one of *hostname* and *servname* must be non-null.

*hints* is an optional pointer to a struct `addrinfo`, as defined by `<netdb.h>`:

```
struct addrinfo {
    int    ai_flags;    /* AI_PASSIVE, AI_CANONNAME, .. */
    int    ai_family;   /* AF_xxx */
    int    ai_socktype; /* SOCK_xxx */
    int    ai_protocol; /* 0 or IPPROTO_xxx for IPv4 and IPv6 */
    socklen_t ai_addrlen; /* length of ai_addr */
    char   *ai_canonname; /* canonical name for hostname */
    struct sockaddr *ai_addr; /* binary address */
    struct addrinfo *ai_next; /* next structure in linked list */
};
```

This structure can be used to provide hints concerning the type of socket that the caller supports or

wishes to use. The caller can supply the following structure elements in *hints*:

- ai\_family* The address family that should be used. When *ai\_family* is set to AF\_UNSPEC, it means the caller will accept any address family supported by the operating system.
- ai\_socktype* Denotes the type of socket that is wanted: SOCK\_STREAM, SOCK\_DGRAM, SOCK\_SEQPACKET, or SOCK\_RAW. When *ai\_socktype* is zero the caller will accept any socket type.
- ai\_protocol* Indicates which transport protocol is desired, IPPROTO\_UDP, IPPROTO\_TCP, IPPROTO\_SCTP, or IPPROTO\_UDPLITE. If *ai\_protocol* is zero the caller will accept any protocol.
- ai\_flags* The *ai\_flags* field to which the *hints* parameter points shall be set to zero or be the bitwise-inclusive OR of one or more of the values AI\_ADDRCONFIG, AI\_ALL, AI\_CANONNAME, AI\_NUMERICHOST, AI\_NUMERICSERV, AI\_PASSIVE and AI\_V4MAPPED. For a UNIX-domain address, *ai\_flags* is ignored.
- AI\_ADDRCONFIG If the AI\_ADDRCONFIG bit is set, IPv4 addresses shall be returned only if an IPv4 address is configured on the local system, and IPv6 addresses shall be returned only if an IPv6 address is configured on the local system.
- AI\_ALL If the AI\_ALL flag is used with the AI\_V4MAPPED flag, then **getaddrinfo()** shall return all matching IPv6 and IPv4 addresses.
- For example, when using the DNS, queries are made for both AAAA records and A records, and **getaddrinfo()** returns the combined results of both queries. Any IPv4 addresses found are returned as IPv4-mapped IPv6 addresses.
- The AI\_ALL flag without the AI\_V4MAPPED flag is ignored.
- AI\_CANONNAME If the AI\_CANONNAME bit is set, a successful call to **getaddrinfo()** will return a NUL-terminated string containing the canonical name of the specified hostname in the *ai\_canonname* element of the first addrinfo structure returned.
- AI\_NUMERICHOST If the AI\_NUMERICHOST bit is set, it indicates that

*hostname* should be treated as a numeric string defining an IPv4 or IPv6 address and no name resolution should be attempted.

**AI\_NUMERICSERV** If the **AI\_NUMERICSERV** bit is set, then a non-null *servname* string supplied shall be a numeric port string. Otherwise, an **EAI\_NONAME** error shall be returned. This bit shall prevent any type of name resolution service (for example, NIS+) from being invoked.

**AI\_PASSIVE** If the **AI\_PASSIVE** bit is set it indicates that the returned socket address structure is intended for use in a call to `bind(2)`. In this case, if the *hostname* argument is the null pointer, then the IP address portion of the socket address structure will be set to **INADDR\_ANY** for an IPv4 address or **IN6ADDR\_ANY\_INIT** for an IPv6 address.

If the **AI\_PASSIVE** bit is not set, the returned socket address structure will be ready for use in a call to `connect(2)` for a connection-oriented protocol or `connect(2)`, `sendto(2)`, or `sendmsg(2)` if a connectionless protocol was chosen. The IP address portion of the socket address structure will be set to the loopback address if *hostname* is the null pointer and **AI\_PASSIVE** is not set.

**AI\_V4MAPPED** If the **AI\_V4MAPPED** flag is specified along with an *ai\_family* of **AF\_INET6**, then **getaddrinfo()** shall return IPv4-mapped IPv6 addresses on finding no matching IPv6 addresses ( *ai\_addrlen* shall be 16).

For example, when using the DNS, if no AAAA records are found then a query is made for A records and any found are returned as IPv4-mapped IPv6 addresses.

The **AI\_V4MAPPED** flag shall be ignored unless *ai\_family* equals **AF\_INET6**.

All other elements of the `addrinfo` structure passed via *hints* must be zero or the null pointer.

If *hints* is the null pointer, **getaddrinfo()** behaves as if the caller provided a struct `addrinfo` with *ai\_family*

set to `AF_UNSPEC` and all other elements set to zero or `NULL`.

After a successful call to **getaddrinfo()**, *\*res* is a pointer to a linked list of one or more `addrinfo` structures. The list can be traversed by following the *ai\_next* pointer in each `addrinfo` structure until a null pointer is encountered. Each returned `addrinfo` structure contains three members that are suitable for a call to `socket(2)`: *ai\_family*, *ai\_socktype*, and *ai\_protocol*. For each `addrinfo` structure in the list, the *ai\_addr* member points to a filled-in socket address structure of length *ai\_addrlen*.

This implementation of **getaddrinfo()** allows numeric IPv6 address notation with scope identifier, as documented in chapter 11 of RFC 4007. By appending the percent character and scope identifier to addresses, one can fill the `sin6_scope_id` field for addresses. This would make management of scoped addresses easier and allows cut-and-paste input of scoped addresses.

At this moment the code supports only link-local addresses with the format. The scope identifier is hardcoded to the name of the hardware interface associated with the link (such as `ne0`). An example is `"fe80::1%ne0"`, which means "fe80::1 on the link associated with the ne0 interface".

The current implementation assumes a one-to-one relationship between the interface and link, which is not necessarily true from the specification.

All of the information returned by **getaddrinfo()** is dynamically allocated: the `addrinfo` structures themselves as well as the socket address structures and the canonical host name strings included in the `addrinfo` structures.

Memory allocated for the dynamically allocated structures created by a successful call to **getaddrinfo()** is released by the **freeaddrinfo()** function. The *ai* pointer should be a `addrinfo` structure created by a call to **getaddrinfo()**.

## IMPLEMENTATION NOTES

The behavior of `freeaddrinfo(NULL)` is left unspecified by both Version 4 of the Single UNIX Specification ("SUSv4") and RFC 3493. The current implementation ignores a `NULL` argument for compatibility with programs that rely on the implementation details of other operating systems.

## RETURN VALUES

**getaddrinfo()** returns zero on success or one of the error codes listed in `gai_strerror(3)` if an error occurs.

## EXAMPLES

The following code tries to connect to "www.kame.net" service "http" via a stream socket. It loops through all the addresses available, regardless of address family. If the destination resolves to an IPv4 address, it will use an `AF_INET` socket. Similarly, if it resolves to IPv6, an `AF_INET6` socket is used.

Observe that there is no hardcoded reference to a particular address family. The code works even if **getaddrinfo()** returns addresses that are not IPv4/v6.

```
struct addrinfo hints, *res, *res0;
int error;
int s;
const char *cause = NULL;

memset(&hints, 0, sizeof(hints));
hints.ai_family = AF_UNSPEC;
hints.ai_socktype = SOCK_STREAM;
error = getaddrinfo("www.kame.net", "http", &hints, &res0);
if (error) {
    errx(1, "%s", gai_strerror(error));
    /* NOTREACHED */
}
s = -1;
for (res = res0; res; res = res->ai_next) {
    s = socket(res->ai_family, res->ai_socktype,
               res->ai_protocol);
    if (s < 0) {
        cause = "socket";
        continue;
    }

    if (connect(s, res->ai_addr, res->ai_addrlen) < 0) {
        cause = "connect";
        close(s);
        s = -1;
        continue;
    }

    break; /* okay we got one */
}
if (s < 0) {
    err(1, "%s", cause);
    /* NOTREACHED */
}
freeaddrinfo(res0);
```

The following example tries to open a wildcard listening socket onto service "http", for all the address families available.

```
struct addrinfo hints, *res, *res0;
int error;
int s[MAXSOCK];
int nsock;
const char *cause = NULL;

memset(&hints, 0, sizeof(hints));
hints.ai_family = AF_UNSPEC;
hints.ai_socktype = SOCK_STREAM;
hints.ai_flags = AI_PASSIVE;
error = getaddrinfo(NULL, "http", &hints, &res0);
if (error) {
    errx(1, "%s", gai_strerror(error));
    /* NOTREACHED */
}
nsock = 0;
for (res = res0; res && nsock < MAXSOCK; res = res->ai_next) {
    s[nsock] = socket(res->ai_family, res->ai_socktype,
        res->ai_protocol);
    if (s[nsock] < 0) {
        cause = "socket";
        continue;
    }

    if (bind(s[nsock], res->ai_addr, res->ai_addrlen) < 0) {
        cause = "bind";
        close(s[nsock]);
        continue;
    }
    (void) listen(s[nsock], 5);

    nsock++;
}
if (nsock == 0) {
    err(1, "%s", cause);
    /* NOTREACHED */
}
```

```
freeaddrinfo(res0);
```
