NAME

delay_output, filter, flushinp, getwin, key_name, keyname, nofilter, putwin, unctrl, use_env, use_tioctl, wunctrl - miscellaneous curses utility routines

SYNOPSIS

```
#include <curses.h>
const char *unctrl(chtype c);
wchar_t *wunctrl(cchar_t *c);

const char *keyname(int c);
const char *key_name(wchar_t w);

void filter(void);
void nofilter(void);

void use_env(bool f);
void use_tioctl(bool f);

int putwin(WINDOW *win, FILE *filep);
WINDOW *getwin(FILE *filep);

int delay_output(int ms);
int flushinp(void);
```

DESCRIPTION

unctrl

The **unctrl** routine returns a character string which is a printable representation of the character c, ignoring attributes. Control characters are displayed in the $^{\Lambda}X$ notation. Printing characters are displayed as is. The corresponding **wunctrl** returns a printable representation of a wide character.

keyname/key_name

The **keyname** routine returns a character string corresponding to the key c:

- Printable characters are displayed as themselves, e.g., a one-character string containing the key.
- \bullet Control characters are displayed in the X notation.
- DEL (character 127) is displayed as ^?.

Values above 128 are either meta characters (if the screen has not been initialized, or if **meta**(3X) has been called with a **TRUE** parameter), shown in the **M-**X notation, or are displayed as themselves. In the latter case, the values may not be printable; this follows the X/Open specification.

- Values above 256 may be the names of the names of function keys.
- Otherwise (if there is no corresponding name) the function returns null, to denote an error. X/Open also lists an "UNKNOWN KEY" return value, which some implementations return rather than null.

The corresponding **key_name** returns a character string corresponding to the wide-character value w. The two functions do not return the same set of strings; the latter returns null where the former would display a meta character.

filter/nofilter

The **filter** routine, if used, must be called before **initscr** or **newterm** are called. Calling **filter** causes these changes in initialization:

- **LINES** is set to 1;
- the capabilities clear, cud1, cud, cup, cuu1, cuu, vpa are disabled;
- the capability **ed** is disabled if **bce** is set;
- and the **home** string is set to the value of **cr**.

The **nofilter** routine cancels the effect of a preceding **filter** call. That allows the caller to initialize a screen on a different device, using a different value of **\$TERM**. The limitation arises because the **filter** routine modifies the in-memory copy of the terminal information.

use_env

The **use_env** routine, if used, should be called before **initscr** or **newterm** are called (because those compute the screen size). It modifies the way **newters** treats environment variables when determining the screen size.

• Normally **neurses** looks first at the terminal database for the screen size.

If **use_env** was called with **FALSE** for parameter, it stops here unless **use_tioctl** was also called with **TRUE** for parameter.

Then it asks for the screen size via operating system calls. If successful, it overrides the values from the terminal database.

Finally (unless use_env was called with FALSE parameter), ncurses examines the LINES or COLUMNS environment variables, using a value in those to override the results from the operating system or terminal database.

Ncurses also updates the screen size in response to **SIGWINCH**, unless overridden by the **LINES** or **COLUMNS** environment variables,

use_tioctl

The **use_tioctl** routine, if used, should be called before **initscr** or **newterm** are called (because those compute the screen size). After **use_tioctl** is called with **TRUE** as an argument, **neurses** modifies the last step in its computation of screen size as follows:

- checks if the **LINES** and **COLUMNS** environment variables are set to a number greater than zero.
- Φ for each, **neurses** updates the corresponding environment variable with the value that it has obtained via operating system call or from the terminal database.
- **ncurses** re-fetches the value of the environment variables so that it is still the environment variables which set the screen size.

The **use_env** and **use_tioctl** routines combine as summarized here:

use envuse tioctlSummary

use_env use_nocusummary		
TRUE	FALSE	This is the default behavior. ncurses uses
		operating system calls unless overridden by
		\$LINES or \$COLUMNS environment variables.
TRUE	TRUE	ncurses updates \$LINES and \$COLUMNS based
		on operating system calls.
FALSE	TRUE	ncurses ignores \$LINES and \$COLUMNS, uses
		operating system calls to obtain size.
FALSE	FALSE	ncurses relies on the terminal database to
		determine size.

putwin/getwin

The **putwin** routine writes all data associated with window (or pad) *win* into the file to which *filep* points. This information can be later retrieved using the **getwin** function.

The **getwin** routine reads window related data stored in the file by **putwin**. The routine then creates and initializes a new window using that data. It returns a pointer to the new window. There are a few caveats:

- the data written is a copy of the **WINDOW** structure, and its associated character cells. The format differs between the wide-character (**ncursesw**) and non-wide (**ncurses**) libraries. You can transfer data between the two, however.
- the retrieved window is always created as a top-level window (or pad), rather than a subwindow.
- the window's character cells contain the color pair *value*, but not the actual color *numbers*. If cells in the retrieved window use color pairs which have not been created in the application using **init_pair**, they will not be colored when the window is refreshed.

delay_output

The **delay_output** routine inserts an *ms* millisecond pause in output. This routine should not be used extensively because padding characters are used rather than a CPU pause. If no padding character is specified, this uses **napms** to perform the delay.

flushinp

The **flushinp** routine throws away any typeahead that has been typed by the user and has not yet been read by the program.

RETURN VALUE

Except for **flushinp**, routines that return an integer return **ERR** upon failure and **OK** (SVr4 specifies only "an integer value other than **ERR**") upon successful completion.

Routines that return pointers return **NULL** on error.

X/Open does not define any error conditions. In this implementation

flushinp

returns an error if the terminal was not initialized.

putwin

returns an error if the associated fwrite calls return an error.

PORTABILITY

filter

The SVr4 documentation describes the action of **filter** only in the vaguest terms. The description here

is adapted from the XSI Curses standard (which erroneously fails to describe the disabling of **cuu**).

keyname

The **keyname** function may return the names of user-defined string capabilities which are defined in the terminfo entry via the **-x** option of **tic**. This implementation automatically assigns at run-time keycodes to user-defined strings which begin with "k". The keycodes start at KEY_MAX, but are not guaranteed to be the same value for different runs because user-defined codes are merged from all terminal descriptions which have been loaded. The **use_extended_names**(3X) function controls whether this data is loaded when the terminal description is read by the library.

nofilter/use_tioctl

The **nofilter** and **use_tioctl** routines are specific to **ncurses**. They were not supported on Version 7, BSD or System V implementations. It is recommended that any code depending on **ncurses** extensions be conditioned using NCURSES_VERSION.

putwin/getwin

The **putwin** and **getwin** functions have several issues with portability:

- The files written and read by these functions use an implementation-specific format. Although the format is an obvious target for standardization, it has been overlooked.
 - Interestingly enough, according to the copyright dates in Solaris source, the functions (along with **scr_init**, etc.) originated with the University of California, Berkeley (in 1982) and were later (in 1988) incorporated into SVr4. Oddly, there are no such functions in the 4.3BSD curses sources.
- Most implementations simply dump the binary WINDOW structure to the file. These include SVr4 curses, NetBSD and PDCurses, as well as older ncurses versions. This implementation (as well as the X/Open variant of Solaris curses, dated 1995) uses textual dumps.

The implementations which use binary dumps use block-I/O (the **fwrite** and **fread** functions). Those that use textual dumps use buffered-I/O. A few applications may happen to write extra data in the file using these functions. Doing that can run into problems mixing block- and buffered-I/O. This implementation reduces the problem on writes by flushing the output. However, reading from a file written using mixed schemes may not be successful.

unctrl/wunctrl

The XSI Curses standard, Issue 4 describes these functions. It states that **unctrl** and **wunctrl** will return a null pointer if unsuccessful, but does not define any error conditions. This implementation checks for three cases:

Φ the parameter is a 7-bit US-ASCII code. This is the case that X/Open Curses documented.

the parameter is in the range 128-159, i.e., a C1 control code. If **use_legacy_coding**(3X) has been called with a **2** parameter, **unctrl** returns the parameter, i.e., a one-character string with the parameter as the first character. Otherwise, it returns "~@", "~A", etc., analogous to "^@", "^A", C0 controls.

X/Open Curses does not document whether **unctrl** can be called before initializing curses. This implementation permits that, and returns the "~@", etc., values in that case.

parameter values outside the 0 to 255 range. **unctrl** returns a null pointer.

The strings returned by **unctrl** in this implementation are determined at compile time, showing C1 controls from the upper-128 codes with a "~" prefix rather than "^". Other implementations have different conventions. For example, they may show both sets of control characters with "^", and strip the parameter to 7 bits. Or they may ignore C1 controls and treat all of the upper-128 codes as printable. This implementation uses 8 bits but does not modify the string to reflect locale. The **use_legacy_coding**(3X) function allows the caller to change the output of **unctrl**.

Likewise, the **meta**(3X) function allows the caller to change the output of **keyname**, i.e., it determines whether to use the "M-" prefix for "meta" keys (codes in the range 128 to 255). Both **use_legacy_coding**(3X) and **meta**(3X) succeed only after curses is initialized. X/Open Curses does not document the treatment of codes 128 to 159. When treating them as "meta" keys (or if **keyname** is called before initializing curses), this implementation returns strings "M-^@", "M-^A", etc.

X/Open Curses documents **unctrl** as declared in **<unctrl.h>**, which **ncurses** does. However, **ncurses**' **<curses.h>** includes **<unctrl.h>**, matching the behavior of SVr4 curses. Other implementations may not do that.

use_env/use_tioctl

If **ncurses** is configured to provide the sp-functions extension, the state of **use_env** and **use_tioctl** may be updated before creating each *screen* rather than once only (**curs_sp_funcs**(3X)). This feature of **use_env** is not provided by other implementation of curses.
