

NAME

getfh, **lgetfh**, **getfhath** - get file handle

LIBRARY

Standard C Library (libc, -lc)

SYNOPSIS

```
#include <sys/param.h>
```

```
#include <sys/mount.h>
```

int

```
getfh(const char *path, fhandle_t *fhp);
```

int

```
lgetfh(const char *path, fhandle_t *fhp);
```

int

```
getfhath(int fd, const char *path, fhandle_t *fhp, int flag);
```

DESCRIPTION

The **getfh()** system call returns a file handle for the specified file or directory in the file handle pointed to by *fhp*.

The **lgetfh()** system call is like **getfh()** except in the case where the named file is a symbolic link, in which case **lgetfh()** returns information about the link, while **getfh()** returns information about the file the link references.

The **getfhath()** system call is equivalent to **getfh()** and **lgetfh()** except when the *path* specifies a relative path. For **getfhath()** and relative *path*, the status is retrieved from a file relative to the directory associated with the file descriptor *fd* instead of the current working directory.

The values for the *flag* are constructed by a bitwise-inclusive OR of flags from this list, defined in *<fcntl.h>*:

AT_SYMLINK_NOFOLLOW

If *path* names a symbolic link, the status of the symbolic link is returned.

AT_RESOLVE_BENEATH

Only walk paths below the directory specified by the *fd* descriptor. See the description of the **O_RESOLVE_BENEATH** flag in the *open(2)* manual page.

If **getfhat()** is passed the special value `AT_FDCWD` in the *fd* parameter, the current working directory is used and the behavior is identical to a call to **getfh()** or **lgetfh()** respectively, depending on whether or not the `AT_SYMLINK_NOFOLLOW` bit is set in *flag*.

When **getfhat()** is called with an absolute *path*, it ignores the *fd* argument.

These system calls are restricted to the superuser.

RETURN VALUES

Upon successful completion, the value 0 is returned; otherwise the value -1 is returned and the global variable *errno* is set to indicate the error.

ERRORS

The **getfh()** and **lgetfh()** system calls fail if one or more of the following are true:

[EPERM]	The caller does not have appropriate privilege to perform the operation.
[ENOTDIR]	A component of the path prefix of <i>path</i> is not a directory.
[ENAMETOOLONG]	The length of a component of <i>path</i> exceeds 255 characters, or the length of <i>path</i> exceeds 1023 characters.
[ENOENT]	The file referred to by <i>path</i> does not exist.
[EACCES]	Search permission is denied for a component of the path prefix of <i>path</i> .
[ELOOP]	Too many symbolic links were encountered in translating <i>path</i> .
[EFAULT]	The <i>fh</i> argument points to an invalid address.
[EFAULT]	The <i>path</i> argument points to an invalid address.
[EIO]	An I/O error occurred while reading from or writing to the file system.
[EINTEGRITY]	Corrupted data was detected while reading from the file system.
[ESTALE]	The file handle <i>fh</i> is no longer valid.

In addition to the errors returned by **getfh()**, and **lgetfh()**, the **getfhat()** system call may fail if:

- [EBADF] The *path* argument does not specify an absolute path and the *fd* argument, is neither AT_FDCWD nor a valid file descriptor open for searching.
- [EINVAL] The value of the *flag* argument is not valid.
- [ENOTDIR] The *path* argument is not an absolute path and *fd* is neither AT_FDCWD nor a file descriptor associated with a directory.
