NAME

rpc_soc, auth_destroy, authnone_create, authunix_create, authunix_create_default, callrpc, clnt_broadcast, clnt_call, clnt_control, clnt_create, clnt_destroy, clnt_freeres, clnt_geterr, clnt_pcreateerror, clnt_perroo, clnt_perroo, clnt_spcreateerror, clnt_sperroo, clnt_spcreate, clntudp_bufcreate, clntudp_create, clntunix_create, get_myaddress, pmap_getmaps, pmap_getport, pmap_rmtcall, pmap_set, pmap_unset, registerrpc, rpc_createerr, svc_destroy, svc_fds, svc_fdset, svc_getargs, svc_getcaller, svc_getreq, svc_getreqset, svc_register, svc_run, svc_sendreply, svc_unregister, svcerr_auth, svcerr_decode, svcerr_noproc, svcerr_noprog, svcerr_progvers, svcerr_systemerr, svcerr_weakauth, svcfd_create, svcunixfd_create, svcraw_create, svcunix_create, xdr_accepted_reply, xdr_authunix_parms, xdr_callhdr, xdr_callmsg, xdr_opaque_auth, xdr_pmap, xdr_pmaplist, xdr_rejected_reply, xdr_replymsg, xprt_register, xprt_unregister - library routines for remote procedure calls

LIBRARY

Standard C Library (libc, -lc)

SYNOPSIS

#include <rpc/rpc.h>

See DESCRIPTION for function declarations.

DESCRIPTION

The svc_*() and clnt_*() functions described in this page are the old, TS-RPC interface to the XDR and RPC library, and exist for backward compatibility. The new interface is described in the pages referenced from rpc(3).

These routines allow C programs to make procedure calls on other machines across the network. First, the client calls a procedure to send a data packet to the server. Upon receipt of the packet, the server calls a dispatch routine to perform the requested service, and then sends back a reply. Finally, the procedure call returns to the client.

Routines that are used for Secure RPC (DES authentication) are described in rpc_secure(3). Secure RPC can be used only if DES encryption is available.

```
void
auth_destroy(AUTH *auth)
```

A macro that destroys the authentication information associated with *auth*. Destruction usually involves deallocation of private data structures. The use of *auth* is undefined after calling **auth_destroy**().

```
AUTH * authnone create()
```

Create and return an RPC authentication handle that passes nonusable authentication information with each remote procedure call. This is the default authentication used by RPC.

```
AUTH *

authunix create(char *host, u int uid, u int gid, int len, u int *aup gids)
```

Create and return an RPC authentication handle that contains UNIX authentication information. The *host* argument is the name of the machine on which the information was created; *uid* is the user's user ID; *gid* is the user's current group ID; *len* and *aup_gids* refer to a counted array of groups to which the user belongs. It is easy to impersonate a user.

```
AUTH * authunix_create_default()
```

Calls **authunix_create()** with the appropriate arguments.

int callrpc(char *host, u_long prognum, u_long versnum, u_long procnum, xdrproc_t inproc, void *in, xdrproc_t outproc, void *out)

Call the remote procedure associated with *prognum*, *versnum*, and *procnum* on the machine *host*. The *in* argument is the address of the procedure's argument(s), and *out* is the address of where to place the result(s); *inproc* is used to encode the procedure's arguments, and *outproc* is used to decode the procedure's results. This routine returns zero if it succeeds, or the value of *enum clnt_stat* cast to an integer if it fails. The routine **clnt_perrno**() is handy for translating failure statuses into messages.

Warning: calling remote procedures with this routine uses UDP/IP as a transport; see **clntudp_create()** for restrictions. You do not have control of timeouts or authentication using this routine.

```
enum clnt_stat
```

Like **callrpc**(), except the call message is broadcast to all locally connected broadcast nets. Each time it receives a response, this routine calls **eachresult**(), whose form is:

bool t eachresult(caddr t out, struct sockaddr in *addr)

where *out* is the same as *out* passed to **clnt_broadcast**(), except that the remote procedure's output is decoded there; *addr* points to the address of the machine that sent the results. If **eachresult**() returns zero, **clnt_broadcast**() waits for more replies; otherwise it returns with appropriate status.

Warning: broadcast sockets are limited in size to the maximum transfer unit of the data link. For ethernet, this value is 1500 bytes.

enum clnt_stat

A macro that calls the remote procedure *procnum* associated with the client handle, *clnt*, which is obtained with an RPC client creation routine such as **clnt_create()**. The *in* argument is the address of the procedure's argument(s), and *out* is the address of where to place the result(s); *inproc* is used to encode the procedure's arguments, and *outproc* is used to decode the procedure's results; *tout* is the time allowed for results to come back.

void clnt destroy(CLIENT *clnt)

A macro that destroys the client's RPC handle. Destruction usually involves deallocation of private data structures, including *clnt* itself. Use of *clnt* is undefined after calling **clnt_destroy**(). If the RPC library opened the associated socket, it will close it also. Otherwise, the socket remains open.

CLIENT *

clnt_create(*char* **host*, *u_long prog*, *u_long vers*, *char* **proto*)

Generic client creation routine. The *host* argument identifies the name of the remote host where the server is located. The *proto* argument indicates which kind of transport protocol to use. The currently supported values for this field are "udp" and "tcp". Default timeouts are set, but can be modified using **clnt_control**().

Warning: Using UDP has its shortcomings. Since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

bool t

clnt_control(CLIENT *cl, u_int req, char *info)

A macro used to change or retrieve various information about a client object. The *req* argument indicates the type of operation, and *info* is a pointer to the information. For both UDP and TCP, the supported values of *req* and their argument types and what they do are:

CLSET_TIMEOUT struct timeval set total timeout CLGET_TIMEOUT struct timeval get total timeout

Note: if you set the timeout using **clnt_control**(), the timeout argument passed to **clnt_call**() will be ignored in all future calls.

CLGET_SERVER_ADDR struct sockaddr_in get server's address

The following operations are valid for UDP only:

CLSET_RETRY_TIMEOUT struct timeval set the retry timeout CLGET_RETRY_TIMEOUT struct timeval get the retry timeout

The retry timeout is the time that UDP RPC waits for the server to reply before retransmitting the request.

bool_t clnt_freeres(CLIENT *clnt, xdrproc_t outproc, char *out)

A macro that frees any data allocated by the RPC/XDR system when it decoded the results of an RPC call. The *out* argument is the address of the results, and *outproc* is the XDR routine describing the results. This routine returns one if the results were successfully freed, and zero otherwise.

void

clnt_geterr(CLIENT *clnt, struct rpc_err *errp)

A macro that copies the error structure out of the client handle to the structure at address *errp*.

void

clnt_pcreateerror(char *s)

prints a message to standard error indicating why a client RPC handle could not be created. The message is prepended with string *s* and a colon. A newline is appended at the end of the message. Used when a **clnt_create()**, **clntraw_create()**, **clnttcp_create()**, or **clntudp_create()** call

fails.

void

clnt_perrno(enum clnt_stat stat)

Print a message to standard error corresponding to the condition indicated by *stat*. A newline is appended at the end of the message. Used after **callrpc**().

```
void clnt_perror(CLIENT *clnt, char *s)
```

Print a message to standard error indicating why an RPC call failed; *clnt* is the handle used to do the call. The message is prepended with string *s* and a colon. A newline is appended at the end of the message. Used after **clnt_call**().

char *
clnt_spcreateerror(char *s)

Like **clnt_pcreateerror**(), except that it returns a string instead of printing to the standard error.

Bugs: returns pointer to static data that is overwritten on each call.

char *
clnt_sperrno(enum clnt_stat stat)

Take the same arguments as **clnt_perrno**(), but instead of sending a message to the standard error indicating why an RPC call failed, return a pointer to a string which contains the message.

The **clnt_sperrno**() function is used instead of **clnt_perrno**() if the program does not have a standard error (as a program running as a server quite likely does not), or if the programmer does not want the message to be output with **printf**(), or if a message format different from that supported by **clnt_perrno**() is to be used.

Note: unlike **clnt_sperror**() and **clnt_spcreateerror**(), **clnt_sperrno**() returns pointer to static data, but the result will not get overwritten on each call.

char *
clnt_sperror(CLIENT *rpch, char *s)

Like **clnt_perror**(), except that (like **clnt_sperrno**()) it returns a string instead of printing to standard error.

Bugs: returns pointer to static data that is overwritten on each call.

CLIENT *

clntraw_create(u_long prognum, u_long versnum)

This routine creates a toy RPC client for the remote program *prognum*, version *versnum*. The transport used to pass messages to the service is actually a buffer within the process's address space, so the corresponding RPC server should live in the same address space; see **svcraw_create()**. This allows simulation of RPC and acquisition of RPC overheads, such as round trip times, without any kernel interference. This routine returns NULL if it fails.

CLIENT *

clnttcp_create(struct sockaddr_in *addr, u_long prognum, u_long versnum, int *sockp, u_int sendsz, u_int recvsz)

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses TCP/IP as a transport. The remote program is located at Internet address *addr*. If *addr->sin_port* is zero, then it is set to the actual port that the remote program is listening on (the remote rpcbind(8) service is consulted for this information). The *sockp* argument is a socket; if it is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*. Since TCP-based RPC uses buffered I/O, the user may specify the size of the send and receive buffers with the *sendsz* and *recvsz* arguments; values of zero choose suitable defaults. This routine returns NULL if it fails.

CLIENT *

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses UDP/IP as a transport. The remote program is located at Internet address *addr*. If *addr->sin_port* is zero, then it is set to actual port that the remote program is listening on (the remote rpcbind(8) service is consulted for this information). The *sockp* argument is a socket; if it is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*. The UDP transport resends the call message in intervals of *wait* time until a response is received or until the call times out. The total time for the call to time out is specified by **clnt_call**().

Warning: since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

CLIENT *

clntudp_bufcreate(struct sockaddr_in *addr, u_long prognum, u_long versnum, struct timeval wait, int *sockp, unsigned int sendsize, unsigned int recosize)

This routine creates an RPC client for the remote program *prognum*, on *versnum*; the client uses UDP/IP as a transport. The remote program is located at Internet address *addr*. If *addr->sin_port* is zero, then it is set to actual port that the remote program is listening on (the remote rpcbind(8) service is consulted for this information). The *sockp* argument is a socket; if it is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*. The UDP transport resends the call message in intervals of *wait* time until a response is received or until the call times out. The total time for the call to time out is specified by **clnt_call**().

This allows the user to specify the maximum packet size for sending and receiving UDP-based RPC messages.

CLIENT *

clntunix_create(struct sockaddr_un *raddr, u_long prognum, u_long versnum, int *sockp, u_int sendsz, u_int recvsz)

This routine creates an RPC client for the local program *prognum*, version *versnum*; the client uses UNIX-domain sockets as a transport. The local program is located at the **raddr*. The *sockp* argument is a socket; if it is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*. Since UNIX-based RPC uses buffered I/O, the user may specify the size of the send and receive buffers with the *sendsz* and *recvsz* arguments; values of zero choose suitable defaults. This routine returns NULL if it fails.

int

get_myaddress(struct sockaddr_in *addr)

Stuff the machine's IP address into *addr*, without consulting the library routines that deal with /*etc/hosts*. The port number is always set to **htons**(*PMAPPORT*). Returns zero on success, non-zero on failure.

```
struct pmaplist *
pmap getmaps(struct sockaddr in *addr)
```

A user interface to the rpcbind(8) service, which returns a list of the current RPC program-to-port mappings on the host located at IP address *addr*. This routine can return NULL. The command "**rpcinfo-p**" uses this routine.

u short

pmap_getport(struct sockaddr_in *addr, u_long prognum, u_long versnum, u_long protocol)

A user interface to the rpcbind(8) service, which returns the port number on which waits a service that supports program number *prognum*, version *versnum*, and speaks the transport protocol associated with *protocol*. The value of *protocol* is most likely IPPROTO_UDP or IPPROTO_TCP. A return value of zero means that the mapping does not exist or that the RPC system failed to contact the remote rpcbind(8) service. In the latter case, the global variable *rpc_createerr* contains the RPC status.

enum clnt_stat

A user interface to the rpcbind(8) service, which instructs rpcbind(8) on the host at IP address *addr* to make an RPC call on your behalf to a procedure on that host. The *portp* argument will be modified to the program's port number if the procedure succeeds. The definitions of other arguments are discussed in **callrpc**() and **clnt_call**(). This procedure should be used for a "ping" and nothing else. See also **clnt_broadcast**().

bool_t pmap_set(u_long prognum, u_long versnum, u_long protocol, u_short port)

A user interface to the rpcbind(8) service, which establishes a mapping between the triple (*prognum*, *versnum*, *protocol*) and *port* on the machine's rpcbind(8) service. The value of *protocol* is most likely IPPROTO_UDP or IPPROTO_TCP. This routine returns one if it succeeds, zero otherwise. Automatically done by **svc_register**().

bool_t pmap_unset(u_long prognum, u_long versnum)

A user interface to the rpcbind(8) service, which destroys all mapping between the triple (*prognum*, *versnum*, *) and *ports* on the machine's rpcbind(8) service. This routine returns one if it succeeds, zero otherwise.

bool_t registerrpc(u_long prognum, u_long versnum, u_long procnum, char *(*procname)(void), xdrproc_t inproc, xdrproc_t outproc)

Register procedure *procname* with the RPC service package. If a request arrives for program *prognum*, version *versnum*, and procedure *procnum*, *procname* is called with a pointer to its argument(s); *progname* should return a pointer to its static result(s); *inproc* is used to decode the arguments while *outproc* is used to encode the results. This routine returns zero if the registration succeeded, -1 otherwise.

Warning: remote procedures registered in this form are accessed using the UDP/IP transport; see **svcudp_create()** for restrictions.

struct rpc_createerr rpc_createerr;

A global variable whose value is set by any RPC client creation routine that does not succeed. Use the routine **clnt_pcreateerror**() to print the reason why.

bool_t svc_destroy(SVCXPRT * xprt)

A macro that destroys the RPC service transport handle, *xprt*. Destruction usually involves deallocation of private data structures, including *xprt* itself. Use of *xprt* is undefined after calling this routine.

fd_set svc_fdset;

A global variable reflecting the RPC service side's read file descriptor bit mask; it is suitable as a template argument to the select(2) system call. This is only of interest if a service implementor does not call **svc_run**(), but rather does his own asynchronous event processing. This variable is read-only (do not pass its address to select(2)!), yet it may change after calls to **svc_getreqset**() or any creation routines. As well, note that if the process has descriptor limits which are extended beyond FD_SETSIZE, this variable will only be usable for the first FD_SETSIZE descriptors.

int svc_fds;

Similar to svc_fdset, but limited to 32 descriptors. This interface is obsoleted by svc_fdset.

bool_t svc_freeargs(SVCXPRT *xprt, xdrproc_t inproc, char *in)

A macro that frees any data allocated by the RPC/XDR system when it decoded the arguments to a service procedure using **svc_getargs**(). This routine returns 1 if the results were successfully freed, and zero otherwise.

bool_t svc_getargs(SVCXPRT *xprt, xdrproc_t inproc, char *in)

A macro that decodes the arguments of an RPC request associated with the RPC service transport handle, *xprt*. The *in* argument is the address where the arguments will be placed; *inproc* is the XDR routine used to decode the arguments. This routine returns one if decoding succeeds, and zero otherwise.

```
struct sockaddr_in *
svc getcaller(SVCXPRT *xprt)
```

The approved way of getting the network address of the caller of a procedure associated with the RPC service transport handle, *xprt*.

```
void svc_getreqset(fd_set *rdfds)
```

This routine is only of interest if a service implementor does not call **svc_run()**, but instead implements custom asynchronous event processing. It is called when the select(2) system call has determined that an RPC request has arrived on some RPC socket(s); *rdfds* is the resultant read file descriptor bit mask. The routine returns when all sockets associated with the value of *rdfds* have been serviced.

```
void svc_getreq(int rdfds)
```

Similar to **svc_getreqset**(), but limited to 32 descriptors. This interface is obsoleted by **svc_getreqset**().

```
bool_t svc_register(SVCXPRT *xprt, u_long prognum, u_long versnum, void (*dispatch)(struct svc_req *, SVCXPRT *), int protocol)
```

Associates *prognum* and *versnum* with the service dispatch procedure, **dispatch**(). If *protocol* is zero, the service is not registered with the rpcbind(8) service. If *protocol* is non-zero, then a mapping of the triple (*prognum*, *versnum*, *protocol*) to *xprt->xp_port* is established with the local rpcbind(8) service (generally *protocol* is zero, IPPROTO_UDP or IPPROTO_TCP). The procedure **dispatch**() has the following form:

```
bool_t dispatch(struct svc_req *request, SVCXPRT *xprt)
```

The **svc_register**() routine returns one if it succeeds, and zero otherwise.

```
svc_run()
```

This routine never returns. It waits for RPC requests to arrive, and calls the appropriate service procedure using **svc_getreq**() when one arrives. This procedure is usually waiting for a select(2) system call to return.

bool_t svc_sendreply(SVCXPRT *xprt, xdrproc_t outproc, char *out)

Called by an RPC service's dispatch routine to send the results of a remote procedure call. The *xprt* argument is the request's associated transport handle; *outproc* is the XDR routine which is used to encode the results; and *out* is the address of the results. This routine returns one if it succeeds, zero otherwise.

void

```
svc_unregister(u_long prognum, u_long versnum)
```

Remove all mapping of the double (*prognum*, *versnum*) to dispatch routines, and of the triple (*prognum*, *versnum*, *) to port number.

void

```
svcerr_auth(SVCXPRT *xprt, enum auth_stat why)
```

Called by a service dispatch routine that refuses to perform a remote procedure call due to an authentication error.

void

```
svcerr_decode(SVCXPRT *xprt)
```

Called by a service dispatch routine that cannot successfully decode its arguments. See also **svc_getargs**().

void

```
svcerr_noproc(SVCXPRT *xprt)
```

Called by a service dispatch routine that does not implement the procedure number that the caller requests.

void

```
svcerr_noprog(SVCXPRT *xprt)
```

Called when the desired program is not registered with the RPC package. Service implementors usually do not need this routine.

void

```
svcerr_progvers(SVCXPRT *xprt, u_long low_vers, u_long high_vers)
```

Called when the desired version of a program is not registered with the RPC package. Service implementors usually do not need this routine.

void

svcerr_systemerr(SVCXPRT *xprt)

Called by a service dispatch routine when it detects a system error not covered by any particular protocol. For example, if a service can no longer allocate storage, it may call this routine.

void

svcerr_weakauth(SVCXPRT *xprt)

Called by a service dispatch routine that refuses to perform a remote procedure call due to insufficient authentication arguments. The routine calls **svcerr_auth**(*xprt*, *AUTH_TOOWEAK*).

SVCXPRT *
svcraw_create(void)

This routine creates a toy RPC service transport, to which it returns a pointer. The transport is really a buffer within the process's address space, so the corresponding RPC client should live in the same address space; see **clntraw_create()**. This routine allows simulation of RPC and acquisition of RPC overheads (such as round trip times), without any kernel interference. This routine returns NULL if it fails.

SVCXPRT *
svctcp_create(int sock, u_int send_buf_size, u_int recv_buf_size)

This routine creates a TCP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the socket *sock*, which may be RPC_ANYSOCK, in which case a new socket is created. If the socket is not bound to a local TCP port, then this routine binds it to an arbitrary port. Upon completion, *xprt->xp_fd* is the transport's socket descriptor, and *xprt->xp_port* is the transport's port number. This routine returns NULL if it fails. Since TCP-based RPC uses buffered I/O, users may specify the size of buffers; values of zero choose suitable defaults.

SVCXPRT *
svcunix create(int sock, u int send buf size, u int recv buf size, char *path)

This routine creates a UNIX-based RPC service transport, to which it returns a pointer. The transport is associated with the socket *sock*, which may be RPC_ANYSOCK, in which case a new socket is created. The *path argument is a variable-length file system pathname of at most 104 characters. This file is *not* removed when the socket is closed. The unlink(2) system call must be used to remove the file. Upon completion, *xprt->xp_fd* is the transport's socket

descriptor. This routine returns NULL if it fails. Since UNIX-based RPC uses buffered I/O, users may specify the size of buffers; values of zero choose suitable defaults.

SVCXPRT * svcunixfd_create(int fd, u_int sendsize, u_int recvsize)

Create a service on top of any open descriptor. The *sendsize* and *recvsize* arguments indicate sizes for the send and receive buffers. If they are zero, a reasonable default is chosen.

```
SVCXPRT *
svcfd_create(int fd, u_int sendsize, u_int recvsize)
```

Create a service on top of any open descriptor. Typically, this descriptor is a connected socket for a stream protocol such as TCP. The *sendsize* and *recvsize* arguments indicate sizes for the send and receive buffers. If they are zero, a reasonable default is chosen.

```
SVCXPRT *
svcudp_bufcreate(int sock, u_int sendsize, u_int recvsize)
```

This routine creates a UDP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the socket *sock*, which may be RPC_ANYSOCK, in which case a new socket is created. If the socket is not bound to a local UDP port, then this routine binds it to an arbitrary port. Upon completion, *xprt->xp_fd* is the transport's socket descriptor, and *xprt->xp_port* is the transport's port number. This routine returns NULL if it fails.

This allows the user to specify the maximum packet size for sending and receiving UDP-based RPC messages.

```
bool_t xdr_accepted_reply(XDR *xdrs, struct accepted_reply *ar)
```

Used for encoding RPC reply messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

```
bool t xdr authunix parms(XDR *xdrs, struct authunix parms *aupp)
```

Used for describing UNIX credentials. This routine is useful for users who wish to generate these credentials without using the RPC authentication package.

```
void
bool_t xdr_callhdr(XDR *xdrs, struct rpc_msg *chdr)
```

Used for describing RPC call header messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

```
bool_t xdr_callmsg(XDR *xdrs, struct rpc_msg *cmsg)
```

Used for describing RPC call messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

```
bool_t xdr_opaque_auth(XDR *xdrs, struct opaque_auth *ap)
```

Used for describing RPC authentication information messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

```
struct pmap;
bool t xdr pmap(XDR *xdrs, struct pmap *regs)
```

Used for describing arguments to various rpcbind(8) procedures, externally. This routine is useful for users who wish to generate these arguments without using the **pmap_***() interface.

```
bool_t xdr_pmaplist(XDR *xdrs, struct pmaplist **rp)
```

Used for describing a list of port mappings, externally. This routine is useful for users who wish to generate these arguments without using the **pmap_***() interface.

```
bool_t xdr_rejected_reply(XDR *xdrs, struct rejected_reply *rr)
```

Used for describing RPC reply messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

```
bool_t xdr_replymsg(XDR *xdrs, struct rpc_msg *rmsg)
```

Used for describing RPC reply messages. This routine is useful for users who wish to generate RPC style messages without using the RPC package.

```
void
xprt_register(SVCXPRT *xprt)
```

After RPC service transport handles are created, they should register themselves with the RPC service package. This routine modifies the global variable *svc_fds*. Service implementors usually do not need this routine.

void

xprt_unregister(SVCXPRT *xprt)

Before an RPC service transport handle is destroyed, it should unregister itself with the RPC service package. This routine modifies the global variable *svc_fds*. Service implementors usually do not need this routine.
