NAME

rpc_soc, **auth_destroy**, **authnone_create**, **authunix_create**, **authunix_create_default**, **callrpc**, **clnt_broadcast**, **clnt_call**, **clnt_control**, **clnt_create**, **clnt_destroy**, **clnt_freeres**, **clnt_geterr**, **clnt_pcreateerror**, **clnt_perrno**, **clnt_perror**, **clnt_spcreateerror**, **clnt_sperrno**, **clnt_sperror**, **clntraw_create**, **clnttcp_create**, **clntudp_bufcreate**, **clntudp_create**, **clntunix_create**, **get_myaddress**, **pmap_getmaps**, **pmap_getport**, **pmap_rmtcall**, **pmap_set**, **pmap_unset**, **registerrpc**, **rpc_createerr**, **svc_destroy**, **svc_fds**, **svc_fdset**, **svc_getargs**, **svc_getcaller**, **svc_getreq**, **svc_getreqset**, **svc_register**, **svc_run**, **svc_sendreply**, **svc_unregister**, **svcerr_auth**, **svcerr_decode**, **svcerr_noproc**, **svcerr_noprog**, **svcerr_progvers**, **svcerr_systemerr**, **svcerr_weakauth**, **svcfd_create**, **svcunixfd_create**, **svcraw_create**, **svcunix_create**, **xdr_accepted_reply**, **xdr_authunix_parms**, **xdr_callhdr**, **xdr_callmsg**, **xdr_opaque_auth**, **xdr_pmap**, **xdr_pmaplist**, **xdr_rejected_reply**, **xdr_replymsg**, **xprt_register**, **xprt_unregister** - library routines for remote procedure calls

LIBRARY

Standard C Library (libc, -lc)

SYNOPSIS

#include <rpc/rpc.h>

See *DESCRIPTION* for function declarations.

DESCRIPTION

The svc_*() and clnt_*() functions described in this page are the old, TS-RPC interface to the XDR and RPC library, and exist for backward compatibility. The new interface is described in the pages referenced from rpc(3).

These routines allow C programs to make procedure calls on other machines across the network. First, the client calls a procedure to send a data packet to the server. Upon receipt of the packet, the server calls a dispatch routine to perform the requested service, and then sends back a reply. Finally, the procedure call returns to the client.

Routines that are used for Secure RPC (DES authentication) are described in rpc_secure(3). Secure RPC can be used only if DES encryption is available.

void
auth_destroy(*AUTH *auth*)

> A macro that destroys the authentication information associated with *auth*. Destruction usually involves deallocation of private data structures. The use of *auth* is undefined after calling **auth_destroy**().

AUTH *
authnone_create()

> Create and return an RPC authentication handle that passes nonusable authentication information
> with each remote procedure call. This is the default authentication used by RPC.

AUTH *
authunix_create(*char *host*, *u_int uid*, *u_int gid*, *int len*, *u_int *aup_gids*)

> Create and return an RPC authentication handle that contains UNIX authentication information.
> The *host* argument is the name of the machine on which the information was created; *uid* is the
> user's user ID; *gid* is the user's current group ID; *len* and *aup_gids* refer to a counted array of
> groups to which the user belongs. It is easy to impersonate a user.

AUTH *
authunix_create_default()

> Calls **authunix_create**() with the appropriate arguments.

int **callrpc**(*char *host*, *u_long prognum*, *u_long versnum*, *u_long procnum*, *xdrproc_t inproc*, *void *in*,
   xdrproc_t outproc, *void *out*)

> Call the remote procedure associated with *prognum*, *versnum*, and *procnum* on the machine *host*.
> The *in* argument is the address of the procedure's argument(s), and *out* is the address of where to
> place the result(s); *inproc* is used to encode the procedure's arguments, and *outproc* is used to
> decode the procedure's results. This routine returns zero if it succeeds, or the value of *enum*
> *clnt_stat* cast to an integer if it fails. The routine **clnt_perrno**() is handy for translating failure
> statuses into messages.
>
> Warning: calling remote procedures with this routine uses UDP/IP as a transport; see
> **clntudp_create**() for restrictions. You do not have control of timeouts or authentication using this
> routine.

enum clnt_stat
clnt_broadcast(*u_long prognum*, *u_long versnum*, *u_long procnum*, *xdrproc_t inproc*, *char *in*,
   xdrproc_t outproc, *char *out*, *bool_t (*eachresult)(caddr_t, struct sockaddr_in *)*)

> Like **callrpc**(), except the call message is broadcast to all locally connected broadcast nets. Each
> time it receives a response, this routine calls **eachresult**(), whose form is:

       bool_t **eachresult**(*caddr_t out*, *struct sockaddr_in *addr*)

       where *out* is the same as *out* passed to **clnt_broadcast**(), except that the remote procedure's output is decoded there; *addr* points to the address of the machine that sent the results. If **eachresult**() returns zero, **clnt_broadcast**() waits for more replies; otherwise it returns with appropriate status.

       Warning: broadcast sockets are limited in size to the maximum transfer unit of the data link. For ethernet, this value is 1500 bytes.

enum clnt_stat
clnt_call(*CLIENT *clnt*, *u_long procnum*, *xdrproc_t inproc*, *char *in*, *xdrproc_t outproc*, *char *out*, *struct timeval tout*)

       A macro that calls the remote procedure *procnum* associated with the client handle, *clnt*, which is obtained with an RPC client creation routine such as **clnt_create**(). The *in* argument is the address of the procedure's argument(s), and *out* is the address of where to place the result(s); *inproc* is used to encode the procedure's arguments, and *outproc* is used to decode the procedure's results; *tout* is the time allowed for results to come back.

void **clnt_destroy**(*CLIENT *clnt*)

       A macro that destroys the client's RPC handle. Destruction usually involves deallocation of private data structures, including *clnt* itself. Use of *clnt* is undefined after calling **clnt_destroy**(). If the RPC library opened the associated socket, it will close it also. Otherwise, the socket remains open.

CLIENT *
clnt_create(*char *host*, *u_long prog*, *u_long vers*, *char *proto*)

       Generic client creation routine. The *host* argument identifies the name of the remote host where the server is located. The *proto* argument indicates which kind of transport protocol to use. The currently supported values for this field are "udp" and "tcp". Default timeouts are set, but can be modified using **clnt_control**().

       Warning: Using UDP has its shortcomings. Since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

bool_t

clnt_control(*CLIENT *cl*, *u_int req*, *char *info*)

A macro used to change or retrieve various information about a client object. The *req* argument indicates the type of operation, and *info* is a pointer to the information. For both UDP and TCP, the supported values of *req* and their argument types and what they do are:

CLSET_TIMEOUT	*struct timeval*	set total timeout
CLGET_TIMEOUT	*struct timeval*	get total timeout

Note: if you set the timeout using **clnt_control**(), the timeout argument passed to **clnt_call**() will be ignored in all future calls.

CLGET_SERVER_ADDR	*struct sockaddr_in*	get server's address

The following operations are valid for UDP only:

CLSET_RETRY_TIMEOUT	*struct timeval*	set the retry timeout
CLGET_RETRY_TIMEOUT	*struct timeval*	get the retry timeout

The retry timeout is the time that UDP RPC waits for the server to reply before retransmitting the request.

bool_t **clnt_freeres**(*CLIENT *clnt*, *xdrproc_t outproc*, *char *out*)

A macro that frees any data allocated by the RPC/XDR system when it decoded the results of an RPC call. The *out* argument is the address of the results, and *outproc* is the XDR routine describing the results. This routine returns one if the results were successfully freed, and zero otherwise.

void
clnt_geterr(*CLIENT *clnt*, *struct rpc_err *errp*)

A macro that copies the error structure out of the client handle to the structure at address *errp*.

void
clnt_pcreateerror(*char *s*)

prints a message to standard error indicating why a client RPC handle could not be created. The message is prepended with string *s* and a colon. A newline is appended at the end of the message. Used when a **clnt_create**(), **clntraw_create**(), **clnttcp_create**(), or **clntudp_create**() call

fails.

void
clnt_perrno(*enum clnt_stat stat*)

>   Print a message to standard error corresponding to the condition indicated by *stat*. A newline is
>   appended at the end of the message. Used after **callrpc**().

void **clnt_perror**(*CLIENT *clnt*, *char *s*)

>   Print a message to standard error indicating why an RPC call failed; *clnt* is the handle used to do
>   the call. The message is prepended with string *s* and a colon. A newline is appended at the end
>   of the message. Used after **clnt_call**().

*char **
clnt_spcreateerror(*char *s*)

>   Like **clnt_pcreateerror**(), except that it returns a string instead of printing to the standard error.

>   Bugs: returns pointer to static data that is overwritten on each call.

*char **
clnt_sperrno(*enum clnt_stat stat*)

>   Take the same arguments as **clnt_perrno**(), but instead of sending a message to the standard error
>   indicating why an RPC call failed, return a pointer to a string which contains the message.

>   The **clnt_sperrno**() function is used instead of **clnt_perrno**() if the program does not have a
>   standard error (as a program running as a server quite likely does not), or if the programmer does
>   not want the message to be output with **printf**(), or if a message format different from that
>   supported by **clnt_perrno**() is to be used.

>   Note: unlike **clnt_sperror**() and **clnt_spcreateerror**(), **clnt_sperrno**() returns pointer to static data,
>   but the result will not get overwritten on each call.

*char **
clnt_sperror(*CLIENT *rpch*, *char *s*)

>   Like **clnt_perror**(), except that (like **clnt_sperrno**()) it returns a string instead of printing to
>   standard error.

Bugs: returns pointer to static data that is overwritten on each call.

*CLIENT ***
clntraw_create(*u_long prognum*, *u_long versnum*)

This routine creates a toy RPC client for the remote program *prognum*, version *versnum*. The transport used to pass messages to the service is actually a buffer within the process's address space, so the corresponding RPC server should live in the same address space; see **svcraw_create**(). This allows simulation of RPC and acquisition of RPC overheads, such as round trip times, without any kernel interference. This routine returns NULL if it fails.

*CLIENT ***
clnttcp_create(*struct sockaddr_in *addr*, *u_long prognum*, *u_long versnum*, *int *sockp*, *u_int sendsz*, *u_int recvsz*)

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses TCP/IP as a transport. The remote program is located at Internet address *addr*. If *addr->sin_port* is zero, then it is set to the actual port that the remote program is listening on (the remote rpcbind(8) service is consulted for this information). The *sockp* argument is a socket; if it is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*. Since TCP-based RPC uses buffered I/O, the user may specify the size of the send and receive buffers with the *sendsz* and *recvsz* arguments; values of zero choose suitable defaults. This routine returns NULL if it fails.

*CLIENT ***
clntudp_create(*struct sockaddr_in *addr*, *u_long prognum*, *u_long versnum*, *struct timeval wait*, *int *sockp*)

This routine creates an RPC client for the remote program *prognum*, version *versnum*; the client uses UDP/IP as a transport. The remote program is located at Internet address *addr*. If *addr->sin_port* is zero, then it is set to actual port that the remote program is listening on (the remote rpcbind(8) service is consulted for this information). The *sockp* argument is a socket; if it is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*. The UDP transport resends the call message in intervals of *wait* time until a response is received or until the call times out. The total time for the call to time out is specified by **clnt_call**().

Warning: since UDP-based RPC messages can only hold up to 8 Kbytes of encoded data, this transport cannot be used for procedures that take large arguments or return huge results.

*CLIENT ***

clntudp_bufcreate(*struct sockaddr_in *addr*, *u_long prognum*, *u_long versnum*, *struct timeval wait*,
      *int *sockp*, *unsigned int sendsize*, *unsigned int recosize*)

      This routine creates an RPC client for the remote program *prognum*, on *versnum*; the client uses
      UDP/IP as a transport. The remote program is located at Internet address *addr*. If
      addr->sin_port is zero, then it is set to actual port that the remote program is listening on (the
      remote rpcbind(8) service is consulted for this information). The *sockp* argument is a socket; if it
      is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*. The UDP transport
      resends the call message in intervals of *wait* time until a response is received or until the call
      times out. The total time for the call to time out is specified by **clnt_call**().

      This allows the user to specify the maximum packet size for sending and receiving UDP-based
      RPC messages.

*CLIENT ***
clntunix_create(*struct sockaddr_un *raddr*, *u_long prognum*, *u_long versnum*, *int *sockp*, *u_int sendsz*,
      u_int recvsz)

      This routine creates an RPC client for the local program *prognum*, version *versnum*; the client
      uses UNIX-domain sockets as a transport. The local program is located at the **raddr*. The *sockp*
      argument is a socket; if it is RPC_ANYSOCK, then this routine opens a new one and sets *sockp*.
      Since UNIX-based RPC uses buffered I/O, the user may specify the size of the send and receive
      buffers with the *sendsz* and *recvsz* arguments; values of zero choose suitable defaults. This
      routine returns NULL if it fails.

int
get_myaddress(*struct sockaddr_in *addr*)

      Stuff the machine's IP address into *addr*, without consulting the library routines that deal with
      /etc/hosts. The port number is always set to **htons**(*PMAPPORT*). Returns zero on success, non-
      zero on failure.

*struct pmaplist ***
pmap_getmaps(*struct sockaddr_in *addr*)

      A user interface to the rpcbind(8) service, which returns a list of the current RPC
      program-to-port mappings on the host located at IP address *addr*. This routine can return NULL.
      The command "**rpcinfo -p**" uses this routine.

u_short

pmap_getport(*struct sockaddr_in *addr*, *u_long prognum*, *u_long versnum*, *u_long protocol*)

>   A user interface to the rpcbind(8) service, which returns the port number on which waits a
>   service that supports program number *prognum*, version *versnum*, and speaks the transport
>   protocol associated with *protocol*. The value of *protocol* is most likely IPPROTO_UDP or
>   IPPROTO_TCP. A return value of zero means that the mapping does not exist or that the RPC
>   system failed to contact the remote rpcbind(8) service. In the latter case, the global variable
>   *rpc_createerr* contains the RPC status.

enum clnt_stat
pmap_rmtcall(*struct sockaddr_in *addr*, *u_long prognum*, *u_long versnum*, *u_long procnum*,
>   *xdrproc_t inproc*, *char *in*, *xdrproc_t outproc*, *char *out*, *struct timeval tout*, *u_long *portp*)

>   A user interface to the rpcbind(8) service, which instructs rpcbind(8) on the host at IP address
>   *addr* to make an RPC call on your behalf to a procedure on that host. The *portp* argument will be
>   modified to the program's port number if the procedure succeeds. The definitions of other
>   arguments are discussed in **callrpc**() and **clnt_call**(). This procedure should be used for a "ping"
>   and nothing else. See also **clnt_broadcast**().

bool_t **pmap_set**(*u_long prognum*, *u_long versnum*, *u_long protocol*, *u_short port*)

>   A user interface to the rpcbind(8) service, which establishes a mapping between the triple
>   (*prognum*, *versnum*, *protocol*) and *port* on the machine's rpcbind(8) service. The value of
>   *protocol* is most likely IPPROTO_UDP or IPPROTO_TCP. This routine returns one if it
>   succeeds, zero otherwise. Automatically done by **svc_register**().

bool_t **pmap_unset**(*u_long prognum*, *u_long versnum*)

>   A user interface to the rpcbind(8) service, which destroys all mapping between the triple
>   (*prognum*, *versnum*, ***) and *ports* on the machine's rpcbind(8) service. This routine returns one if
>   it succeeds, zero otherwise.

bool_t **registerrpc**(*u_long prognum*, *u_long versnum*, *u_long procnum*, *char *(*procname)(void)*,
>   *xdrproc_t inproc*, *xdrproc_t outproc*)

>   Register procedure *procname* with the RPC service package. If a request arrives for program
>   *prognum*, version *versnum*, and procedure *procnum*, *procname* is called with a pointer to its
>   argument(s); *progname* should return a pointer to its static result(s); *inproc* is used to decode the
>   arguments while *outproc* is used to encode the results. This routine returns zero if the
>   registration succeeded, -1 otherwise.

Warning: remote procedures registered in this form are accessed using the UDP/IP transport; see **svcudp_create**() for restrictions.

struct rpc_createerr rpc_createerr;

A global variable whose value is set by any RPC client creation routine that does not succeed. Use the routine **clnt_pcreateerror**() to print the reason why.

bool_t **svc_destroy**(*SVCXPRT * xprt*)

A macro that destroys the RPC service transport handle, *xprt*. Destruction usually involves deallocation of private data structures, including *xprt* itself. Use of *xprt* is undefined after calling this routine.

fd_set svc_fdset;

A global variable reflecting the RPC service side's read file descriptor bit mask; it is suitable as a template argument to the select(2) system call. This is only of interest if a service implementor does not call **svc_run**(), but rather does his own asynchronous event processing. This variable is read-only (do not pass its address to select(2)!), yet it may change after calls to **svc_getreqset**() or any creation routines. As well, note that if the process has descriptor limits which are extended beyond FD_SETSIZE, this variable will only be usable for the first FD_SETSIZE descriptors.

int svc_fds;

Similar to *svc_fdset*, but limited to 32 descriptors. This interface is obsoleted by *svc_fdset*.

bool_t **svc_freeargs**(*SVCXPRT *xprt*, *xdrproc_t inproc*, *char *in*)

A macro that frees any data allocated by the RPC/XDR system when it decoded the arguments to a service procedure using **svc_getargs**(). This routine returns 1 if the results were successfully freed, and zero otherwise.

bool_t **svc_getargs**(*SVCXPRT *xprt*, *xdrproc_t inproc*, *char *in*)

A macro that decodes the arguments of an RPC request associated with the RPC service transport handle, *xprt*. The *in* argument is the address where the arguments will be placed; *inproc* is the XDR routine used to decode the arguments. This routine returns one if decoding succeeds, and zero otherwise.

struct sockaddr_in *
svc_getcaller(*SVCXPRT *xprt*)

> The approved way of getting the network address of the caller of a procedure associated with the RPC service transport handle, *xprt*.

void **svc_getreqset**(*fd_set *rdfds*)

> This routine is only of interest if a service implementor does not call **svc_run**(), but instead implements custom asynchronous event processing. It is called when the select(2) system call has determined that an RPC request has arrived on some RPC socket(s); *rdfds* is the resultant read file descriptor bit mask. The routine returns when all sockets associated with the value of *rdfds* have been serviced.

void **svc_getreq**(*int rdfds*)

> Similar to **svc_getreqset**(), but limited to 32 descriptors. This interface is obsoleted by **svc_getreqset**().

bool_t **svc_register**(*SVCXPRT *xprt*, *u_long prognum*, *u_long versnum*,
  void (*dispatch)(struct svc_req *, SVCXPRT *), *int protocol*)

> Associates *prognum* and *versnum* with the service dispatch procedure, **dispatch**(). If *protocol* is zero, the service is not registered with the rpcbind(8) service. If *protocol* is non-zero, then a mapping of the triple (*prognum*, *versnum*, *protocol*) to *xprt->xp_port* is established with the local rpcbind(8) service (generally *protocol* is zero, IPPROTO_UDP or IPPROTO_TCP). The procedure **dispatch**() has the following form:

> > *bool_t* **dispatch**(*struct svc_req *request*, *SVCXPRT *xprt*)

> The **svc_register**() routine returns one if it succeeds, and zero otherwise.

svc_run()

> This routine never returns. It waits for RPC requests to arrive, and calls the appropriate service procedure using **svc_getreq**() when one arrives. This procedure is usually waiting for a select(2) system call to return.

bool_t **svc_sendreply**(*SVCXPRT *xprt*, *xdrproc_t outproc*, *char *out*)

Called by an RPC service's dispatch routine to send the results of a remote procedure call. The *xprt* argument is the request's associated transport handle; *outproc* is the XDR routine which is used to encode the results; and *out* is the address of the results. This routine returns one if it succeeds, zero otherwise.

void
svc_unregister(*u_long prognum*, *u_long versnum*)

Remove all mapping of the double (*prognum*, *versnum*) to dispatch routines, and of the triple (*prognum*, *versnum*, *) to port number.

void
svcerr_auth(*SVCXPRT *xprt*, *enum auth_stat why*)

Called by a service dispatch routine that refuses to perform a remote procedure call due to an authentication error.

void
svcerr_decode(*SVCXPRT *xprt*)

Called by a service dispatch routine that cannot successfully decode its arguments. See also **svc_getargs**().

void
svcerr_noproc(*SVCXPRT *xprt*)

Called by a service dispatch routine that does not implement the procedure number that the caller requests.

void
svcerr_noprog(*SVCXPRT *xprt*)

Called when the desired program is not registered with the RPC package. Service implementors usually do not need this routine.

void
svcerr_progvers(*SVCXPRT *xprt*, *u_long low_vers*, *u_long high_vers*)

Called when the desired version of a program is not registered with the RPC package. Service implementors usually do not need this routine.

void
svcerr_systemerr(*SVCXPRT *xprt*)

> Called by a service dispatch routine when it detects a system error not covered by any particular
> protocol. For example, if a service can no longer allocate storage, it may call this routine.

void
svcerr_weakauth(*SVCXPRT *xprt*)

> Called by a service dispatch routine that refuses to perform a remote procedure call due to
> insufficient authentication arguments. The routine calls **svcerr_auth**(*xprt*, *AUTH_TOOWEAK*).

*SVCXPRT **
svcraw_create(*void*)

> This routine creates a toy RPC service transport, to which it returns a pointer. The transport is
> really a buffer within the process's address space, so the corresponding RPC client should live in
> the same address space; see **clntraw_create**(). This routine allows simulation of RPC and
> acquisition of RPC overheads (such as round trip times), without any kernel interference. This
> routine returns NULL if it fails.

*SVCXPRT **
svctcp_create(*int sock*, *u_int send_buf_size*, *u_int recv_buf_size*)

> This routine creates a TCP/IP-based RPC service transport, to which it returns a pointer. The
> transport is associated with the socket *sock*, which may be RPC_ANYSOCK, in which case a
> new socket is created. If the socket is not bound to a local TCP port, then this routine binds it to
> an arbitrary port. Upon completion, *xprt->xp_fd* is the transport's socket descriptor, and
> *xprt->xp_port* is the transport's port number. This routine returns NULL if it fails. Since
> TCP-based RPC uses buffered I/O, users may specify the size of buffers; values of zero choose
> suitable defaults.

*SVCXPRT **
svcunix_create(*int sock*, *u_int send_buf_size*, *u_int recv_buf_size*, *char *path*)

> This routine creates a UNIX-based RPC service transport, to which it returns a pointer. The
> transport is associated with the socket *sock*, which may be RPC_ANYSOCK, in which case a
> new socket is created. The **path* argument is a variable-length file system pathname of at most
> 104 characters. This file is *not* removed when the socket is closed. The unlink(2) system call
> must be used to remove the file. Upon completion, *xprt->xp_fd* is the transport's socket

descriptor. This routine returns NULL if it fails. Since UNIX-based RPC uses buffered I/O, users may specify the size of buffers; values of zero choose suitable defaults.

SVCXPRT *
svcunixfd_create(*int fd*, *u_int sendsize*, *u_int recvsize*)

Create a service on top of any open descriptor. The *sendsize* and *recvsize* arguments indicate sizes for the send and receive buffers. If they are zero, a reasonable default is chosen.

SVCXPRT *
svcfd_create(*int fd*, *u_int sendsize*, *u_int recvsize*)

Create a service on top of any open descriptor. Typically, this descriptor is a connected socket for a stream protocol such as TCP. The *sendsize* and *recvsize* arguments indicate sizes for the send and receive buffers. If they are zero, a reasonable default is chosen.

SVCXPRT *
svcudp_bufcreate(*int sock*, *u_int sendsize*, *u_int recvsize*)

This routine creates a UDP/IP-based RPC service transport, to which it returns a pointer. The transport is associated with the socket *sock*, which may be RPC_ANYSOCK, in which case a new socket is created. If the socket is not bound to a local UDP port, then this routine binds it to an arbitrary port. Upon completion, *xprt->xp_fd* is the transport's socket descriptor, and *xprt->xp_port* is the transport's port number. This routine returns NULL if it fails.

This allows the user to specify the maximum packet size for sending and receiving UDP-based RPC messages.

bool_t **xdr_accepted_reply**(*XDR *xdrs*, *struct accepted_reply *ar*)

Used for encoding RPC reply messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t **xdr_authunix_parms**(*XDR *xdrs*, *struct authunix_parms *aupp*)

Used for describing UNIX credentials. This routine is useful for users who wish to generate these credentials without using the RPC authentication package.

void
bool_t **xdr_callhdr**(*XDR *xdrs*, *struct rpc_msg *chdr*)

Used for describing RPC call header messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t **xdr_callmsg**(*XDR *xdrs*, *struct rpc_msg *cmsg*)

Used for describing RPC call messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t **xdr_opaque_auth**(*XDR *xdrs*, *struct opaque_auth *ap*)

Used for describing RPC authentication information messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

struct pmap;
bool_t **xdr_pmap**(*XDR *xdrs*, *struct pmap *regs*)

Used for describing arguments to various rpcbind(8) procedures, externally. This routine is useful for users who wish to generate these arguments without using the **pmap_***() interface.

bool_t **xdr_pmaplist**(*XDR *xdrs*, *struct pmaplist **rp*)

Used for describing a list of port mappings, externally. This routine is useful for users who wish to generate these arguments without using the **pmap_***() interface.

bool_t **xdr_rejected_reply**(*XDR *xdrs*, *struct rejected_reply *rr*)

Used for describing RPC reply messages. This routine is useful for users who wish to generate RPC-style messages without using the RPC package.

bool_t **xdr_replymsg**(*XDR *xdrs*, *struct rpc_msg *rmsg*)

Used for describing RPC reply messages. This routine is useful for users who wish to generate RPC style messages without using the RPC package.

void
xprt_register(*SVCXPRT *xprt*)

After RPC service transport handles are created, they should register themselves with the RPC service package. This routine modifies the global variable *svc_fds*. Service implementors usually do not need this routine.

void
xprt_unregister(*SVCXPRT *xprt*)

> Before an RPC service transport handle is destroyed, it should unregister itself with the RPC service package. This routine modifies the global variable *svc_fds*. Service implementors usually do not need this routine.
